

What You Will Need:

Test Card for your most important hypothesis

Your experiment 'artefact'

Data collecting device or worksheet

Learning Card for your observations

Your Turn - Run Experiments and Collect Evidence

In the previous lesson you designed an experiment for your most important hypothesis. It's time now to run that experiment and collect data.

TOTAL TIME: Every experiment has a specific run time to generate sufficient evidence that you can learn from.

 [Print Directions](#)

Directions

1. Run the Experiment

As you run your experiments, you collect qualitative and/or quantitative data. The way you collect and code that data can have a big impact on the quality of your evidence.

- **Qualitative data:** For interviews and other experiments that produce qualitative data, we recommend that you create a worksheet that allows you to take notes while you conduct your experiment. This will help you code qualitative data in the most efficient way possible.
- **Quantitative data:** Make sure you have a reliable instrument of measurement (e.g. Google Analytics) and that you carefully tag your data correctly from the beginning of your experiment to avoid a messy data set. Collect as many data points as possible.

Make sure you run your experiments almost like a scientist, so that your evidence is clean and not misleading.

2. Analyze & Synthesize the Evidence

Evidence does not speak on its own. Gather the evidence you have from different experiments for a specific hypothesis and analyze it.

Keep a copy of your detailed evidence. You then code your evidence, and find common themes in order to write a summary of your observations in your [Learning Card](#):

- **Coding** helps us group similar pieces of evidence.
- **Themes** are like 'headers' for each group of similar evidence.
- **Affinity Mapping** is a great technique for coding qualitative data, and finding themes.
- Write down your 'themes' in the 'observations' block in the **Learning Card**.
